ГЕОИНФОРМАЦИОННЫЕ СИСТЕМЫ И КОСМИЧЕСКИЙ МОНИТОРИНГ

PROCESSING AND ANALYSIS OF REMOTE SENSING DATA IN ORDER TO OBTAIN RELEVANT INFORMATION ON THE CHARACTERISTICS AND CONDITION OF THE FOREST FUND

# Shershniovskoe forestry case study

## Shershniovskoe forestry. Geospatial dataset

On the example of the Shershniovskoe forestry (Chelyabinsk Oblast) we have approved technologies for processing and analysis of remote sensing data in order to obtain relevant information on the characteristics and condition of the forest fund.

The territory of the forestry is located in the South-Ural area of the forest steppe zone.

Forestry's Forest Fund is represented by distributed over the territory forest areas of various sizes.

Average woodiness is 21,4%.

## Shershniovskoe forestry

We used several sets of satellite imagery to cover the whole forestry territory:

•actual high-resolution data obtained by WorldView-2 and GeoEye-1 satellites,

•actual data obtained by the RapidEye constellation,

•multiple coverage of Landsat-TM/ETM+(4-8) images (1987 - 2014 acquisition period) for the retrospective territory analysis.

## Conclusion

The result is a set of vector and raster data describing the current status of the territory. Such information help in many areas:

The Local Department of Forestry can monitor the activities of forest managers, make timely changes to the forest inventory materials. Forest users, in turn, may adjust the forest management plans taking into account the negative processes occurring in the forests.

Using the information about negative processes we can do some preventive activities, organize alert of the population, attract the attention of specialized services, prevent dangerous situations.

Providing the scientific community with input data and results of monitoring will clarify the used methodology and will contribute to the development and introduction of new approaches to monitoring.
